Description

[0001] This invention relates to a diaper having a mechanical fastener comprising a loop member.

[0002] Japanese Patent Application Disclosure No. 1997-317 describes a female tape comprising a web substantially made of heat-sealable conjugated fibers, the web being formed with sealing zones so that one surface of the web may be densified and the other surface may be formed with a plurality of loop elements.

[0003] The female tape described in this Japanese Patent Application Disclosure No. 1997-317 adopts heat-sealable staple fibers of eccentric core-sheath type having a length of 64 mm as the fibers constituting the web. With this construction, the fibers having their ends out of the sealing zones may readily fall off and cause napping in such region. As a result, the hook member may be easily separated from the loop member.

[0004] US Patent 5,256,231 and European Patent Application 0 341 993 both disclose loop element fasteners, comprising longitudinally arranged elongate fibers and bonding zones arranged in a series of parallel lines.

[0005] It is an object of this invention to provide a diaper having a mechanical fastener comprising a loop member practically free from falling off of fibers and enabling a hook member to be reliably anchored on the loop member.

According to this invention, there is provided a diaper having a mechanical fastener comprising a hook member and a loop member adapted to be releasably engaged with the hook member, said loop member comprising a base sheet having: a first plurality of continuous filaments extending on one surface of said base sheet substantially parallel one to another in a first direction, said first plurality of filaments being bonded to said base sheet along at least a first pair of bonding zones extending transversely of said filaments to form a first plurality of loop elements extending between said first pair of bonding zones; and a second plurality of continuous filaments extending on one surface of said base sheet substantially parallel one to another in a second direction said second plurality of filament being bonded to said base sheet along at least a pair of second bonding zones extending transversely of said filaments to form a second plurality of loop elements extending between said second pair of bonding zones, characterised in that the first and second directions are substantially orthogonal to one another.

[0006] According to one preferred embodiment of this invention, the loop elements are formed by the filaments rounding out above the base sheet between pair of bonding zones.

[0007] According to another embodiment of this invention, the loop elements are bonded to the base sheet along at least a pair of bonding zones extending parallel to the filaments.

[0008] According to still another embodiment of this

invention, the base sheet is divided at least in two sections so that the filaments lying in one of the two sections extend so as to intersect the filaments lying in the other section.

[0009] According to a further embodiment of this invention, each of the filaments has a length of 1 - 30 mm as measured between the bonding zones.

[0010] According to an additional embodiment of this invention, the filaments has a fineness of 0.5 ~ 60.0 deniers and a basis weight of 20 - 150 g/m².

[0011] According to still additional embodiment of this invention, each of the bonding zones has a width of 0.5 ~ 5.0 mm.

[0012] According to further additional embodiment of this invention, the filaments are obtained by deregistering a continuous filament two.

[0013] Details of a diaper with a mechanical fastener comprising a loop member according to this invention will be more fully understood from the description given hereunder with reference to the accompanying drawings, of which:

Fig. 1 is a perspective view of part of a loop member for use with a diaper in accordance with the present invention;

Fig. 2 is a sectional view taken along line A - A in Fig. 1;

Fig. 3 is a view similar to Fig. 1 showing a loop member for use with a diaper in accordance with the present invention;

Fig. 4 is a perspective view of a disposable diaper in accordance with the present invention, adopting the loop member shown by Fig. 3; and

Fig. 5 is a sectional view taken along a line B - B in Fig. 4.

[0014] Referring to figure 1, the loop member 1 is of a rectangular shape defined by transversely opposite side edges 1a extending parallel to each other and longitudinally opposite ends 1b extending substantially parallel to each other and orthogonally of the side edges 1a. The loop member 1 comprises a heat-sealable base sheet 3 and a plurality of heat-sealable continuous filaments 2 arranged on one surface of the base sheet 3 extending one direction parallel one to another.

[0015] With this loop member 1, a plurality of bonding zones 5 are arranged at substantially regular intervals between the transversely opposite side edges 1a of the loop member 1 substantially parallel to the filaments 2. Similarly, a plurality of bonding zones 6 are arranged at substantially regular intervals between the longitudinally opposite ends 1b orthogonally of the filaments 2. Along these bonding zones 5, 6, the filaments 2 are bonded to the base sheet 3 so that these filaments 2 may partially round out above the base sheet 3 between each pair of the adjacent bonding zones 6 and thereby form a plurality of loop elements 4a. These bonding zones 5, 6 defines a plurality of loop-crowded regions 4 independent

3

EP 1 048 236 B1

4

ent one from another. The filaments 2 partially round out above the base sheet 3 because these filaments 2 are initially layered and bulky and such filaments 2 are bonded to the base sheet 2 partially under pressure.

[0016] Bonding of the filaments 2 to the base sheet 3 is performed using ultrasonic- or heat-sealing technique and along the respective bonding zones 5, 6, the base sheet 3 sealed with the filaments 2 together. As a result, the filaments 2 lose their initial forms and become filmy along the bonding zones 5, 6 while the bonding zones 5 define compressed grooves.

[0017] With this loop member 1, when a hook member (not shown) formed with a plurality of hook elements is pressed against the loop member 4, the hook elements are inserted into gaps among the loop elements 4a and caught by these loop elements 4a so that the hook member may be anchored on the loop member 1. The hook member may be pulled away from the loop member 1 to disengage the respective hook elements from the respective loop elements 4a and thereby to separate the hook member from the loop member 1.

[0018] There is no concern that one or more filaments might fall off from the loop-crowded regions 4 which might consequently become fluffy unless the filaments are snapped or worn. This is for the reason that none of the filament ends exists in the loop-crowded regions 4.

[0019] The filaments 2 may have a length of 1 ~ 30 mm as measured between each pair of the adjacent bonding zones 6. The length less than 1 mm would be too short to form the loop elements 4a. The length larger than 30 mm would cause the loop elements 4a to be readily slacken, resulting in disengagement of the hooks from the loop elements 4a.

[0020] A fineness of the filaments 2 may be in a range of 0.5 ~ 60.0 deniers. With the fineness less than 0.5 deniers, a strength of the filaments 2 would excessively decrease, possibly resulting in breakage of the filaments 2 as the hook elements are being separated from the loop elements 4a. With the fineness larger than 60.0 deniers, it would sometimes impossible to engage the hook elements with the loop elements 4a, depending on a size of the hook elements.

[0021] A basis weight of the filaments 2 may be in a range of 20 ~ 150 g/m². With the basis weight less than 20 g/m², a density of the filaments 2, i.e., the number of the loop elements 4a per unit area would be insufficient to ensure a reliable engagement between the loop member 1 and the hook member. With the basis weight larger than 150 g/m², a density of the filaments 2, i.e., a bulkiness of the loop-crowded regions 4 would be unacceptably increased and the loop elements 4a would prevent the hook elements from being sufficiently inserted into the gaps among the loop elements 4a to ensure the firm engagement between the loop member 1 and the hook member.

[0022] The bonding zones 5 as well as the bonding zones 6 may have a width L of 0.5 ~ 5.0 mm. With the width less than 0.5 mm, the filaments 2 would easily get

out of the respective bonding zones 5, 6 and it is concerned that the filaments 2 might be peeled off from the base sheet 3 along the bonding zones 5, 6. With the width larger than 5.0 mm, an area ratio of the bonding zones 5, 6 to the loop member 1 would be too high to ensure a predetermined area over which the loop-crowded regions 4 should be formed on the loop member 1.

[0023] The loop member 1 is not limited to that of the rectangular shape as illustrated but may be of the other shape such as of polygonal, circular or oval shape. It is possible without departing from the scope of this invention to bond the filaments 2 to the base sheet 3 only along the bonding zones 6. It is not essential for this invention that the bonding zones 5 and the bonding zones 6 should extend substantially parallel to and orthogonally of the filaments 2, respectively, and this invention covers also the case in which these bonding zones 5, 6 extend obliquely of the filaments 2.

[0024] Fig. 3 is a view similar to Fig. 1 showing another embodiment of the loop member 1. According to this embodiment, an entire area of the loop member 1 is divided in two substantially equal sections 7, 8. In the section 7, a plurality of filaments 2 extend substantially parallel to the bonding zones 5 and, in the section 8, a plurality of filaments 2 extend substantially parallel to the bonding zones 6. In the case of the loop member 1 according to this embodiment, the filaments 2 lying substantially the section 7 extend orthogonally of the filaments 2 lying in the section 8 wherein the filaments 2 are bonded to the base sheet 3 along the bonding zones 5, 6. The particular bonding zones 5 substantially bisecting a dimension between the transversely opposite side edges 1a defines a boundary line of these two sections 7, 8.

[0025] Fig. 4 is a perspective view of a disposable diaper 20 adopting the loop member 1 shown in Fig. 3 and Fig. 5 is a sectional view taken along line B - B in Fig. 4. Fig. 4 illustrates two situations in which the loop member 1 and a tape fastener 12 are in engagement with each other and not in engagement with each other. The diaper 20 is provided on transversely opposite side edges of a front waist region 10 with the loop members 1 bonded to a backsheet 14 by means of an adhesive agent 15. On the other hand, the diaper 20 is provided on transversely opposite side edges of a rear waist region 11 with the tape fasteners 12 having their proximal ends bonded to the backsheet 14. The loop members 1 function as pieces of target tape for the associated tape fasteners 12. The respective tape fasteners 12 are provided on their free ends with hook members 13 which are, in turn, formed with a plurality of mushroom-shaped hook elements 13a. As seen on the left hand of Fig. 5, these hook elements 13a are caught by the loop elements 4a.

[0026] In the section 7, the filaments 2 extend longitudinally of the diaper 20. Such arrangement is effective to keep the loop member 1 and the hook member 13 in

5

EP 1 048 236 B1

6

firm engagement with each other even if the diaper 20 put on the wearer's body is placed under tension directed transversely of the diaper 20, depending on movement of the wearer's body.

[0027] In the section 8, the filaments 2 extend transversely of the diaper 20. Such an arrangement is effective to keep the loop member 1 and the hook member 13 in firm engagement with each other even if the diaper 20 put on the wearer's body is placed under tension directed longitudinally of the diaper 20, depending on movement of the wearer's body.

[0028] It is possible without departing from the scope of this invention to divide the loop member 1 in more than two sections. In this case, the filaments 2 lying in one of each pair of the adjacent sections preferably extend so as to intersect the filaments 2 lying in the other section. For example, it is also possible to modify the arrangement of Fig. 3 so that the filaments 2 lying in one of each pair of the adjacent loop-crowded regions 4 extend so as to intersect the filaments 2 lying in the other loop-crowded region 4.

[0029] Stock material for the base sheet 3 may be selected from a group consisting of a nonwoven fabric made of heat-sealable fibers, a heat-sealable plastic film and a laminated sheet obtained from these nonwoven fabric and plastic film. Stock material for the continuous filament 2 may be selected from a group consisting of various kinds of deregistered or opened tow formed by two-layer conjugated fibers of side-by-side type or core-sheath type and multilayer conjugated fibers of multi-core type or archipelago type wherein the conjugated fibers may be of, for example, polyolefine, polyester or polyamide. Each of the loop elements 4a formed by the registered tow preferably has one crimp/cm in order that the hook element can be reliably caught by the loop element 4a.

[0030] When the filaments 2 are bonded to the base sheet 3 using the heat-sealing technique as in the embodiment described herein, the continuous filament 2 preferably comprises conjugated fibers of core-sheath type wherein its core is formed by polypropylene fibers and its sheath is formed by polyethylene fibers having its m.p. lower than that of polypropylene fibers. The filament 2 can be bonded to the base sheet 3 by melting not polypropylene fibers but polyethylene fibers only and it is not concerned that the filaments 2 might be snapped or worn in the bonding zones 6, 7.

[0031] Bonding the filaments 2 to the base sheet 3 can be achieved also using a suitable adhesive agent such as hot melt adhesive or glue. When the filaments 2 are bonded to the base sheet 3 using an adhesive agent or glue, the filaments 2 as well as the base sheet 3 may be formed by material other than the heat-sealable material.

[0032] The loop member according to this invention enables the hook elements formed on the hook member to be easily caught by the filaments on the loop member and thereby enables the hook member to be reliably an-

chored on the loop member, since the loop elements are formed by a plurality of continuous filaments. Neither falling off of the filaments from the loop elements nor napping on the loop member occurs as the hook member is peeled off from the loop member.

Claims

1. A diaper (20) having a mechanical fastener comprising a hook member (13) and a loop member (1) adapted to be releasably engaged with the hook member (13), said loop member (1) comprising a base sheet (3) having:

a first plurality of continuous filaments (2) extending on one surface of said base sheet (3) substantially parallel one to another in a first direction, said first plurality of filaments (2) being bonded to said base sheet (3) along at least a first pair of bonding zones (6) extending transversely of said filaments (2) to form a first plurality of loop elements (4a) extending between said first pair of bonding zones (6); and a second plurality of continuous filaments (2) extending on one surface of said base sheet (3) substantially parallel one to another in a second direction said second plurality of filament (2) being bonded to said base sheet (3) along at least a pair of second bonding zones (5) extending transversely of said filaments (2) to form a second plurality of loop elements (4a) extending between said second pair of bonding zones (6), characterised in that the first and second directions are substantially orthogonal to one another.

2. The diaper (20) according to Claim 1, wherein said first and second loop elements (4a) are formed by said filaments (2) rounding out above the base sheet (3) between pair of bonding zones (5,5; 6,6).

3. The diaper (20) according to Claim 1, wherein said first and second loop elements (2) are bonded to said base sheet (3) along at least a pair of bonding zones (6,6; 5,5) extending substantially parallel to said filaments (2).

4. The diaper (20) according to Claim 1, wherein said base sheet is divided at least in two sections (7, 8) so that said filaments lying in one of said two sections extend so as to intersect said filaments lying in the other section.

5. The diaper (20) according to Claim 1, wherein said first and second filament (2) have a length of 1 - 30 mm as measured between said bonding zones (5,5; 6,6).

7

EP 1 048 236 B1

8

6. The diaper (20) according to Claim 1, wherein said first and second filaments (2) have a fineness of 0.5 ~ 60.0 deniers and a basis weight of 20 ~ 150 g/m².
7. The diaper according to Claim 1, wherein each of said first and second bonding zones (5,5; 6,6) has a width of 0.5 ~ 5.0 mm.
8. The diaper according to Claim 1, wherein said filaments (2) are obtained by deregistering a continuous filament into two.

Patentansprüche

1. Windel (20) mit einem mechanischen Verschuß mit einem Hakenteil (13) und einem Schlaufenteil (1), das lösbar in das Hakenteil (13) eingreifen kann, wobei das Schlaufenteil (1) eine Basislage (3) enthält, die folgendes aufweist:

eine erste Vielzahl kontinuierlicher Fäden (2), die auf einer Fläche der Basislage (3) im wesentlichen parallel zueinander in eine erste Richtung verlaufen und entlang mindestens eines ersten Paares quer zu den Fäden (2) verlaufender Bondzonen (6) unter Bildung einer ersten Vielzahl an Schlaufenelementen (4a), die zwischen den Bondzonen (6) des ersten Paares verlaufen, an die Basislage (3) gebondet sind; und eine zweite Vielzahl kontinuierlicher Fäden (2), die auf einer Fläche der Basislage (3) im wesentlichen parallel zueinander in eine zweite Richtung verlaufen und entlang mindestens einem Paar quer zu den Fäden (2) verlaufender zweiter Bondzonen (5) unter Bildung einer zweiten Vielzahl an Schlaufenelementen (4a), die zwischen den Bondzonen (5) des zweiten Paares verlaufen, an die Basislage (3) gebondet sind, dadurch gekennzeichnet, daß die erste und die zweite Richtung im wesentlichen orthogonal zueinander sind.

2. Windel (20) nach Anspruch 1, wobei die ersten und die zweiten Schlaufenelemente (4a) dadurch gebildet sind, daß sich die Fäden (2) zwischen einem Paar Bondzonen (5,5; 6,6) nach oben auswölben.
3. Windel (20) nach Anspruch 1, wobei die ersten und die zweiten Schlaufenelemente (2) entlang mindestens einem Paar Bondzonen (6,6; 5,5), die im wesentlichen parallel zu den Fäden (2) verlaufen, an die Basislage (3) gebondet sind.
4. Windel (20) nach Anspruch 1, wobei die Basislage mindestens in zwei Abschnitte (7, 8) geteilt ist, so daß die in einem der beiden Abschnitte liegenden Fäden so verlaufen, daß sie die in dem anderen Ab-

schnitt liegenden Fäden schneiden.

5. Windel (20) nach Anspruch 1, wobei die ersten und die zweiten Fäden (2) zwischen den Bondzonen (5,5; 6,6) gemessen eine Länge von 1 bis 30 mm aufweisen.
6. Windel (20) nach Anspruch 1, wobei die ersten und die zweiten Fäden (2) eine Feinheit von 0,5 bis 60,0 Deniers und ein Grundgewicht von 20 bis 150 g/m² aufweisen.
7. Windel (20) nach Anspruch 1, wobei die ersten und zweiten Bondzonen (5,5; 6,6) jeweils eine Breite von 0,5 bis 5,0 mm aufweisen.
8. Windel (20) nach Anspruch 1, wobei die Fäden (2) durch Auftrennen eines kontinuierlichen Fadens in zwei erhalten sind.

Revendications

1. Couche-culotte (20) pourvue d'une fixation mécanique comprenant un élément à crochets (13) et un élément à boucles (1) apte à être accroché de façon détachable avec l'élément à crochets (13), ledit élément à boucles (1) comprenant une feuille de base (3) qui comprend:

une première pluralité de filaments continus (2) s'étendant sur l'une des surfaces de ladite feuille de base (3) sensiblement parallèlement les uns aux autres dans une première direction, ladite première pluralité de filaments (2) étant attachée à ladite feuille de base (3) le long d'au moins une première paire de zones d'attache (6) s'étendant transversalement auxdits filaments (2) pour former une première pluralité d'éléments à boucles (4a) s'étendant entre les zones d'attache (6) de ladite première paire; et une deuxième pluralité de filaments continus (2) s'étendant sur l'une des surfaces de ladite feuille de base (3) sensiblement parallèlement les uns aux autres dans une deuxième direction, ladite deuxième pluralité de filaments (2) étant attachée à ladite feuille de base (3) le long d'au moins une paire de deuxièmes zones d'attache (5) s'étendant transversalement auxdits filaments (2) pour former une deuxième pluralité d'éléments à boucles (4a) s'étendant entre les zones d'attache (5) de ladite deuxième paire; caractérisée en ce que les première et deuxième directions sont sensiblement orthogonales entre elles.

2. Couche-culotte (20) selon la revendication 1, dans laquelle lesdits premiers et deuxièmes éléments à

9

EP 1 048 236 B1

10

boucles (4a) sont formés par lesdits filaments (2) qui s'arrondissent vers l'extérieur au dessus de la feuille de base (3) entre deux zones d'attache (5,5; 6,6) formant une paire.

5

3. Couche-culotte (20) selon la revendication 1, dans laquelle lesdits premiers et deuxièmes éléments à boucles (2) sont attachés à ladite feuille de base (3) le long d'au moins une paire de zones d'attache (6, 6; 5, 5) s'étendant sensiblement parallèlement auxdits filaments (2). 10
4. Couche-culotte (20) selon la revendication 1, dans laquelle ladite feuille de base est divisée au moins en deux sections (7, 8) d'une manière telle que lesdits filaments disposés dans une première desdites deux sections s'étend de manière à couper lesdits filaments disposés dans l'autre section. 15
5. Couche-culotte (20) selon la revendication 1, dans laquelle la longueur desdits filaments (2), mesurée entre lesdits zones d'attache (5, 5; 6, 6), est de 1 à 30 mm. 20
6. Couche-culotte (20) selon la revendication 1, dans laquelle la finesse desdits premiers et deuxièmes filaments (2) est de 0,5 à 60,0 deniers, et leur poids de base est de 20 à 150 g/m². 25
7. Couche-culotte (20) selon la revendication 1, dans laquelle la largeur desdites premières et deuxièmes zones d'attache (5, 5; 6,6) est de 0,5 à 5,0 mm. 30
8. Couche-culotte (20) selon la revendication 1, dans laquelle lesdits filaments (2) sont obtenus en désassemblant un filament continu en deux composants. 35
